Does patient have symptom(s) of vitamin D deficiency?
- Gradual onset and persistent musculoskeletal pain (often in back or lower limbs)
- Proximal muscle weakness
- Waddling gait

Is the patient in one of the following high risk groups?
- Osteoporosis patients who will be, or who are being, prescribed potent antiresorptive agents (e.g. zoledronic acid or denosumab)
- Osteomalacia
- On certain medication that may, for example, decrease bone mineral density, increase risk of osteomalacia, increase vitamin D metabolism, or interfere with vitamin D absorption (e.g. rifampicin, highly active antiretrovirals, antiepileptics, cholestyramine, glucocorticoids, antifungals)

Does patient fall into another risk category?
- Age >65 years
- Pregnant
- Breastfeeding
- Low or no exposure to the sun (e.g. those who cover their skin for cultural reasons; housebound patients; care home residents)
- Pigmented skin (e.g. people of African, African-Caribbean or South Asian origin)
- Risk of falls

Investigations: Serum 25-OHD; bone profile (Ca²⁺, PO₄); U&Es; LFTs

Deficiency: 25-OHD level <25nmol/L

Insufficiency: 25-OHD level 25-50nmol/L

Adequate: 25-OHD level >50nmol/L

Recommend vitamin D supplements that can be purchased, as well as providing lifestyle advice (see overleaf for additional information)
- Regular, safe, sun exposure
- Dietary sources of vitamin D
- Vitamin D supplements 1,000 – 2,000 units daily. Select 1,000 units daily where 25-OHD level lower to 50nmol/L, and 2,000 units daily where 25-OHD level lower to 25nmol/L. (Ideally recommend patient to purchase—see options overhead)
- Supplemental calcium is not required for most patients, but ensure adequate calcium intake for those at risk of osteoporosis (e.g. postmenopausal women, vegans, and those on bisphosphonate therapy)
- Consider retesting serum 25-OHD after a minimum of 3 months in deficient patients, insufficient patients remaining symptomatic, and patients on anti-epileptics
- Seek advice from secondary care for patients remaining deficient/insufficient who have been compliant with treatment
- Monitor bone profile, electrolytes, and 25-OHD annually and review need for continued supplementation

Treat deficiency by prescribing by brand as:
- Biovitamin D3 20,000 units capsules* (vitamin D3; colecalferal)
  DOSE: 2 capsules orally once daily for 14 days (capsules contain gelatine) (approx. £8 per course)
- OR, for patients who cannot swallow capsules, or who are vegetarian/vegan:
  - Sterogyl liquid 20,000 units/ml** (vitamin D2; ergocalciferol)
  DOSE: 2mL orally once daily for 14 days (approx. £8 per course from Oxford Pharmacy Stores; price may vary depending on wholesaler used)

In patients with corrected calcium levels >2.50mmol/L vitamin D replacement should only be initiated with advice from secondary care. Check Ca²⁺ after 4 weeks in these patients.

Maintenance therapy following treatment

Refer to secondary care if the patient has (this list is not exhaustive):
- Malabsorption syndromes, short bowel or cholestatic liver disease
  - Adjusted doses may be required
- Primary Hyperparathyroidism
  - Vitamin D replacement: Initiate in secondary care due to risk of worsening hypercalcaemia; treatment can be continued in primary care
  - Vitamin D maintenance: Use preparations that contain vitamin D only
- Chronic Kidney Disease (CKD) (eGFR<30ml/min/1.73m²)

Do not routinely check vitamin D levels if asymptomatic

Provide lifestyle advice (see overleaf for additional information)
- Regular, safe, sun exposure
- Dietary sources of vitamin D
- Consider recommending vitamin D supplements where appropriate (see below) that can be purchased (see overleaf for suitable products)
- Ensure adequate vitamin D plus calcium supplementation for those with or at risk of osteoporosis (e.g. postmenopausal women, vegans, and those on bisphosphonate therapy), where the optimal 25-OHD level is >75nmol/L

The Department of Health recommends vitamin D supplementation for the following groups:
- People aged 65 years and over and people who are not exposed to much sun—take a daily supplement containing 400 units (10mcg) of vitamin D
- All pregnant and breastfeeding women—take a daily supplement containing 400 units (10mcg) of vitamin D

The MHRA recommends that vitamin D supplementation is considered for at-risk patients who receive treatment with primidone, phenytoin, carbamazepine, phenobarbital, or sodium valproate.

* Does not have UK marketing authorisation; marketed as a nutritional supplement
** Does not have UK marketing authorisation; manufactured and licensed by DB Pharma, France
**Sun Exposure**

- Over 90% of the body’s vitamin D is produced from the action of sunlight on the skin; sun exposure (where burning does not occur and no sun protection is used) between 10am to 3pm from April to October for 5-15mins should be sufficient to improve vitamin D status.
- In a fair skinned person, 20-30 minutes of sunlight exposure to the face and forearms at midday generates about 2000 units (50mcg) of vitamin D.
- Two or three sunlight exposures per week can achieve adequate vitamin D levels in the summer so long as the individuals have sufficient levels to begin with. The elderly, and those with a deficiency or pigmented skin, will need an increased exposure time or frequency to achieve an adequate level of vitamin D.
- Unprotected sun exposure should be avoided in patients with xeroderma pigmentosum. The risks and benefits of sun exposure for those with a history of skin cancer or actinic keratosis will need to be carefully considered.

**Dietary Sources**

- Excellent food sources (greater than 200 units (5mcg) per portion of vitamin D) include 2 teaspoons of cod liver oil, 70g sardines tinned in tomato sauce or oil (drained), 100g tinned salmon, pilchards or tuna, 110g of cooked mackerel or herring, and 130g cooked kipper. Other sources include egg yolks, mushrooms, fortified breakfast cereals, milk, and margarine.

### Examples of adult vitamin D nutritional supplements available to purchase
